STELLER'S SEA-EAGLE  

*Haliaeetus pelagicus*

non-breeding visitor, vagrant  

monotypic

Steller's Sea-Eagles breed in Siberia and winter S to Japan (Dement'ev and Gladkov 1951b, AOU 1998). Wandering individuals have been recorded in Alaska SE to the Juneau area, probably on Wake Atoll in winter 1997 (Rauzon et al. 2008), and in the *Northwestern Hawaiian Islands*, where two individuals have been recorded at three atolls.

Following a period of strong winds and heavy rain an exhausted and water-soaked Steller's Sea-Eagle arrived on Green Island, *Kure*, in early Feb 1978 and remained through 2 Mar (Balazs and Ralph 1979; HRBP 0023, 0024, 0526, 0527, published *E* 39:117-118 and R. Pyle 1979). Coast Guard staff observed it predate an adult albatross and found freshly eaten remains of additional adult *Laysan* and *Black-footed* albatrosses. The eagle then moved to *Midway* where it was first reported 20 Mar 1978 on Sand I. It spent time on both Sand and Eastern Is, and was photographed being harassed by *White Terns* in April (HRBP 1449-1450, 5043). Comparison of photographs indicates this to be the same individual, probably a fourth-spring bird molting into definitive plumage. It was last reported at Midway during the first half of May 1978. Subsequently, an adult Steller's Sea-Eagle was well described at Tern Island, *French Frigate* 4-12 Nov 1983. It perched during one of the nights in the rigging of a boat moored in the lagoon.
